

PHYS-3301 Homework 5 Due 15 Oct 2014

This homework is due in the dropbox outside 2L26 by 11:59PM on the due date. You may email a PDF (typed or black-and-white scanned) or give a hardcopy to Dr. Frey.

1. A Moving Object *Barton 6.6 plus*

A relativistic car moves along the x axis, passing $x = 0$ at $t = 0$. Its velocity is $u(t) = dx/dt = c/\cosh(\omega t)$. **Important:** In the following, you will find some integrals involving hyperbolic trig functions. You may use computer programs such as Maple or Mathematica to do them *only* if you *cite the program you use and check the result of the indefinite integral by differentiating it and seeing that you get the integrand.*

- Sketch the worldline of the car on a spacetime diagram. Can a real car follow this path exactly?
- Find the relation between the time t and the car's proper time τ . Choose integration constants so that $\tau = 0$ when $t = 0$. Be careful taking signs if you take a square root.
- Find u as a function of τ and $dx/d\tau$. *Hint:* Remember that $u = dx/dt$, not $dx/d\tau$.
- Since the car moves, it doesn't experience as much proper time as coordinate time t . Find the total time lag Δ over all time, which is defined as

$$\Delta = \lim_{t \rightarrow \infty} [t - \tau(t)] - \lim_{t \rightarrow -\infty} [t - \tau(t)] .$$

2. Ultrarelativistic Velocity Addition *from Hogg 4.8*

A neutral pion particle (π^0) of mass M is produced at rest with respect to the lab frame. In one possible but rare decay, it produces an electron and positron (anti-electron) which move off in opposite directions, each with mass m and relativistic γ factor of $\gamma = M/2m \approx 100$.

- Since γ is so large, the speed of the electron or positron relative to the lab can be written as $u/c = 1 - \epsilon$. Find ϵ to the lowest order in the small number m/M (that is, if ϵ is written as a power series in m/M , find the power series out to the lowest power with a nonzero coefficient) and then to 1 significant digit.
- Relative to the electron, what is the positron's speed? Again, write the relative speed as $u/c = 1 - \tilde{\epsilon}$ and find $\tilde{\epsilon}$ to lowest order in m/M and to 1 significant digit.

3. Gene and George

George Lucas and Gene Roddenberry decide to race each other from Earth to Mars over a distance d . Lucas travels in a straight line from Earth to Mars at constant speed, while Roddenberry travels along a semicircle of radius $d/2$ at constant speed. Roddenberry's ship is faster, though, so both arrive at Mars at the same time ($t = T$ in the common rest frame of Earth and Mars). Label Earth's position as $x = -d/2$ and Mars's position as $x = d/2$.

- Who has aged more during the trip? Explain your answer qualitatively.
- Assuming our two racers leave Earth at $t = 0$ in the Earth-Mars frame, write Roddenberry's position and velocity as functions of time t and his proper time τ . Assume that Roddenberry moves in the (x, y) plane.
- What is Roddenberry's velocity in Lucas's rest frame?
- Finally, find Roddenberry's proper time τ as a function of Lucas's rest frame time t' .
