

• The Action + Lagrangian Mechanics

- The Action + Hamilton's Principle

• The Lagrangian function

+ Let's think about some key quantities of Newtonian mechanics.

$$\vec{p} = m\vec{\dot{x}}, \quad T = \frac{1}{2}m\dot{\vec{x}}^2, \quad \vec{F} = -\vec{\nabla}V(\vec{x}) \text{ (when conservative)}$$

+ Newton's 2nd law is of course $\dot{\vec{p}} = \vec{F}$.

But we have another relationship we've previously

ignored given by $p_i = \partial T / \partial \dot{x}_i$.

+ We can rewrite the 2nd law as $\frac{d}{dt}(\partial T / \partial \dot{x}_i) = -\partial V / \partial x_i$

+ We can define the Lagrangian function

$$L = T - V \quad (*)$$

so the eqn of motion is

$$\frac{d}{dt}(\partial L / \partial \dot{x}_i) - \partial L / \partial x_i = 0$$

which takes the form of Euler-Lagrange eqns.

+ Although we are for now defining L as $(*)$ for normal conservative forces, and the usual $v^2/2m$ kinetic energy, physicists often takes L to be the fundamental quantity + allows more general functions. We'll see some later.

• Hamilton's principle

+ The fact that Newton's 2nd law can be recast as an $E=L$ eqn, suggest we define a functional, the action

$$S = \int_{t_0}^{t_f} dt L(t, \vec{x}, \vec{\dot{x}})$$

+ Hamilton's Principle (of least action) states that the actual path of a particle moving from \vec{x}_0 to \vec{x}_f from time t_0 to t_f is the path that minimizes the action functional

+ In some cases, the physical path may be another type of extremum, but typically it is a minimum

+ Here's the advantage of minimizing an action vs using Newton's laws: the action/Lagrangian are scalars. We can use generalized coordinates immediately without having to worry about unit vectors in those directions, what the acceleration looks like, etc (think about spherical coords)

+ To deal with constraints, we can introduce generalized coordinates q_i or Lagrange multipliers λ and add appropriate terms to L

• Some interpretation:

+ Newtonian + Lagrangian mechanics are equivalent even though they are formulated differently. (General proof later.) Lagrangian mechanics gives a global meaning to the differential (local) form of Newtonian mechanics.

+ The E-L eqns are essentially the 2nd law in general coordinates: define

$$p_i = \partial L / \partial \dot{q}_i \equiv \text{canonical momentum (for } q_i \text{)}$$

(angular mom. if $q_i = \text{angle}$, etc)

$$Q_i = \partial L / \partial q_i \equiv \text{generalized forces}$$

(again, may be torques, etc)

$$\text{Then } \dot{p}_i = Q_i$$

+ Lagrange multipliers typically contribute forces of constraint to Q_i \leftarrow we'll see these later

+ Non-conservative forces like friction also add to Q_i but are not part of $\partial L / \partial q_i$

- Examples:

• Simple Pendulum: A bob a fixed radius $r=l$ from a support

+ The speed of the circular motion is $l\dot{\theta}$ in terms

+ of the polar angle

+ the potential is $V = mgl(1 - \cos\theta)$, so Lagrangian

is
$$L = \frac{1}{2} m l^2 \dot{\theta}^2 - mgl(1 - \cos\theta)$$

+ The E-L equation is $m l^2 \ddot{\theta} + mgl \sin\theta = 0$ as expected

+ We could also use a Lagrange multiplier to set $r=l$.

Then the modified Lagrangian is

$$L' = \frac{1}{2} m \dot{r}^2 + \frac{1}{2} m r^2 \dot{\theta}^2 - mgl(1 - r \cos\theta) - \lambda(r - l)$$

+ The E-L eqn for θ is unchanged once we use $r=l = \text{const.}$

for the λ eqn. The r E-L eqn is

$$m v^2/r = m l \dot{\theta}^2 = -mg \cos\theta + \lambda$$

The Lagrange multiplier λ is equal to the tension keeping the bob on a circle!

• Pendulum on Moving support: previous example

+ The pendulum support has mass M and moves frictionlessly on a track along the x axis w/ position X

+ The bob is at fixed radius $r=l$ and angle θ from the vertical wr.t. the instantaneous support position. Bob mass = m

These are standard pendulum variables in the accelerating support frame.

+ In a Newtonian analysis, we need tension T of pendulum.

We have

$$M \ddot{X} = T \sin\theta$$

$$\sum m l \ddot{\theta} = -mg \sin\theta - m \ddot{X} \cos\theta$$

$$T = -m \ddot{X} \sin\theta + mg \cos\theta$$

This includes the fictitious force in the support's frame.

We can eliminate T , then mg from 1st eqn

+ Alternatively, we recall the bob's position is given by

$$x = X + l \sin\theta, \quad y = -l \cos\theta$$

$$\Rightarrow \ddot{x} = \ddot{X} + l \cos\theta \ddot{\theta}, \quad \ddot{y} = +l \sin\theta \ddot{\theta}$$

$$L = \frac{1}{2} M \dot{X}^2 + \frac{1}{2} m (\dot{X}^2 + l^2 \dot{\theta}^2 + 2l \dot{X} \dot{\theta} \cos \theta) + mgl \cos \theta$$

+ the eqn of motion are

$$\frac{d}{dt} [(M+m) \dot{X} + ml \dot{\theta} \cos \theta] = 0$$

$$\begin{aligned} \frac{d}{dt} [ml^2 \ddot{\theta} + ml \dot{X} \cos \theta] &= ml \dot{X} \dot{\theta} \sin \theta + mgl \sin \theta = 0 \\ &= ml^2 \ddot{\theta} + ml \dot{X} \cos \theta + mgl \sin \theta = 0 \end{aligned}$$

This already has the simplifications above automatically
 - we never had to think about tension (force of constraint)
 + Can think about interpretation of EOM + check consistency with various limits

+ Note that the Lagrangian formalism with these coordinates automatically accounts for the accelerating frame. Also, b/c \dot{X} does not depend on X , there is a conserved quantity

• Double Atwood Machine: This is a pulley connecting two masses plus another mass hanging from another pulley. What are the accelerations?

+ The constraints are that the strings over the pulleys are fixed length.
 So the positions of m_1 and pulley M_2

are x and $l_1 - x$, while the positions of the lower $m_2 + m_3$ masses are $l_1 - x + y$ and $l_1 - x + l_2 - y$.

The angular position of pulley 1 is $\theta = x/R_1$, and the angular position of pulley 2 is $\phi = y/R_2$.

+ The kinetic energy is therefore

$$T = \frac{1}{2} m_1 \dot{x}^2 + \frac{1}{2} M_2 \dot{x}^2 + \frac{1}{2} m_2 (\dot{y} - \dot{x})^2 + \frac{1}{2} m_3 (\dot{y} + \dot{x})^2 + \frac{1}{2} I_1 \dot{x}^2 / R_1^2 + \frac{1}{2} I_2 \dot{y}^2 / R_2^2$$

And potential energy is

$$V = -m_1 g x - M_2 g (l_1 - x) - m_2 g (l_1 - x + y) - m_3 g (l_1 + l_2 - x - y)$$

so

$$L = \frac{1}{2} (m_1 + M_2 + \frac{I_1}{R_1^2} + m_2 + m_3) \dot{x}^2 + \frac{1}{2} (m_2 + m_3 + \frac{I_2}{R_2^2}) \dot{y}^2 + (m_3 - m_2) \dot{y} \dot{x} + (m_1 - M_2 - m_2 - m_3) g x + (m_2 - m_3) g y + \text{const.}$$

+ The EOM are therefore

$$(m_1 + M_2 + m_1 + m_3 + \frac{I_1}{R_1^2}) \ddot{x} + (m_3 - m_2) \ddot{y} = (m_1 - M_2 - m_1 - m_3) g$$

$$(m_2 + m_3 + \frac{I_2}{R_2^2}) \ddot{y} + (m_3 - m_2) \ddot{x} = (m_2 - m_3) g$$

We can solve for \ddot{x} , \ddot{y} and then plug back into the 3 mass accelerations \ddot{x} , $\ddot{y} - \ddot{x}$, and $-\ddot{y} - \ddot{x}$.

• Spherical Pendulum: Like Foucault's pendulum, this is a pendulum allowed to swing in any direction at a fixed length l from a fixed support. Alternatively, it is an object sliding w/o friction in a spherical bowl.

+ If θ is the polar angle from the downward vertical axis, and ϕ is the azimuthal angle,

$$L = \frac{1}{2} m l^2 (\dot{\theta}^2 + \sin^2 \theta \dot{\phi}^2) + m g l (1 - \cos \theta)$$

+ Since L does not depend on ϕ , the angular momentum

$$p_\phi = \partial L / \partial \dot{\phi} = m l^2 \sin^2 \theta \dot{\phi}$$

is conserved.

+ We can now take 2 approaches to analyze the motion.

One is to set the θ EEqn

$$\begin{aligned} m l^2 \ddot{\theta} &= m l^2 \dot{\phi}^2 \sin \theta \cos \theta - m g l \sin \theta \\ &= -m g l \sin \theta + p_\phi^2 \cos \theta / m l^2 \sin^3 \theta \end{aligned}$$

You can then analyze in various approximations, such as simple pendulum limit, oscillation around + precession of a circular orbit, etc.

You may notice that this follows from an effective potential if you segregate.

+ Be careful NOT to plug the angular momentum back into the Lagrangian first. Using

$$L = \frac{1}{2} m l^2 \dot{\theta}^2 + \left[\frac{1}{2} p_\phi^2 / m l^2 \sin^2 \theta - m g l (1 - \cos \theta) \right]$$

gives the wrong EOM. Generally, only plug EOM back in special circumstances.

• Things to note:

- + With the right coordinates, we don't have to worry about things like normal forces, tensions, etc that only enforce constraints
 - + If you use Lagrange multipliers, the value you find for them is the value of the constraint force.
 - + If your coordinates correspond to use of an accelerating frame, the E-L eqns automatically include the fictitious forces
 - + If L is independent of coordinate q , momentum $p = \frac{\partial L}{\partial \dot{q}}$ is conserved
- Equivalence with Newtonian Mechanics

• We already saw this for unconstrained Cartesian coords. \vec{x} and conservative forces. Let's see for general coords. For simplicity, we'll assume:

- + We can solve constraints by choice of coords (holonomic), can generalize to Lagrange multipliers.
- + Assume that forces other than forces of constraint are conservative. Will discuss this at the end.
- + The system is natural, so $x_i(\{q\}, t)$ actually has $\partial x_i / \partial t = 0$. Can easily add this back

• Start with canonical momentum

+ With our assumptions, $L = T(q, \dot{q}) - V(q)$
 where $T = \frac{1}{2} m \dot{\vec{x}}^2$ in Cartesian coordinates with $\vec{x} = \vec{x}(q)$

+ Therefore,

$$p_i = \partial L / \partial \dot{q}_i = \partial T / \partial \dot{q}_i = m \sum_j \dot{x}_j \partial x_j / \partial \dot{q}_i$$

+ But $\dot{x}_j = \sum_i (\partial x_j / \partial \dot{q}_i) \dot{q}_i \Rightarrow \partial x_j / \partial \dot{q}_i = \partial x_j / \partial \dot{q}_i$

so $p_i = m \sum_j \dot{x}_j \partial x_j / \partial \dot{q}_i$

• The E-L eqn has form

$$\frac{d}{dt} (\partial L / \partial \dot{q}_i) = \partial L / \partial q_i = \sum_j \frac{\partial T}{\partial x_j} \frac{\partial x_j}{\partial q_i} + \sum_k \frac{\partial V}{\partial x_k} \frac{\partial x_k}{\partial q_i}$$

$$= m \sum_j \ddot{x}_j \frac{\partial x_j}{\partial \dot{q}_i} + m \sum_{j,k} \dot{x}_j \frac{\partial^2 x_j}{\partial x_k \partial q_i} \dot{q}_k$$

+ The 1st of these is given by the force

$$m \sum_j \ddot{x}_j \frac{\partial x_j}{\partial q_i} = \sum_j F_j \frac{\partial x_j}{\partial q_i}$$

+ The 2nd term contains (by commutativity of partials)

$$\sum_k \frac{\partial \dot{x}_k}{\partial q_i \partial q_i} \dot{q}_k = \sum_k \frac{\partial \dot{x}_k}{\partial q_i \partial q_k} \dot{q}_k = \frac{\partial}{\partial q_i} \left(\sum_k \frac{\partial x_k}{\partial q_k} \dot{q}_k \right) = \frac{\partial \dot{x}_j \frac{\partial x_j}{\partial q_i}}{\partial q_i \partial q_i} \dot{q}_i$$

Therefore, the 2nd term is $\sum_j m \dot{x}_j \frac{\partial \dot{x}_j}{\partial q_i} = \partial T / \partial q_i$

• What are the forces?

+ Divide \vec{F} into conservative forces $-\vec{\nabla}V$ and constraint forces \vec{F}'

+ Constraint forces for holonomic ^{natural} constraints act to stop the coordinates from moving off a surface $\vec{x}(q)$, so they act \perp to the surface. But $\partial x_j / \partial q_i$ are always tangent to the surface

+ Therefore

$$\begin{aligned} \sum_j F_j \frac{\partial x_j}{\partial q_i} &= \sum_j \left(F'_j + \frac{\partial V}{\partial x_j} \right) \frac{\partial x_j}{\partial q_i} \\ &= -\frac{\partial V}{\partial q_i} = Q_i \text{ generalized force.} \end{aligned}$$

• Altogether, we have

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}_i} \right) = -\frac{\partial V}{\partial q_i} + \frac{\partial T}{\partial q_i} = \frac{\partial L}{\partial q_i}$$

+ If there are nonconservative, non constraint forces \vec{F}_j , like kinetic friction, these don't follow from a Lagrangian. We have to modify the E-L eqn to

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}_i} \right) - \frac{\partial L}{\partial q_i} = \hat{Q}_i$$

where $\hat{Q}_i = \sum_j F_j \frac{\partial x_j}{\partial q_i}$ (in the

+ Some nonconservative forces can be described by letting $V = V(q, \dot{q})$. See next! (you could also possibly generalize T)

- Electromagnetism

- The Lorentz force is conservative only b/c the magnetic force does no work. But we can define a potential anyway

- We recall/learn that

$$\vec{E} = -\vec{\nabla}\Phi - \frac{\partial \vec{A}}{\partial t}, \quad \vec{B} = \vec{\nabla} \times \vec{A}$$

where Φ = (electric) scalar potential, \vec{A} = vector potential

- Consider the potential $V(\vec{x}, \dot{\vec{x}}) = q\Phi(\vec{x}, t) - q\dot{\vec{x}} \cdot \vec{A}(\vec{x}, t)$
We want to write the force

$$+ \text{The } \vec{F}_i = q(\vec{E} + \dot{\vec{x}} \times \vec{B})_i = -\frac{\partial V}{\partial x_i} + \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}_i} \right)$$

- + We can examine $x_i = x$ in Cartesian coords

$$\begin{aligned} \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}} \right) &= -q \frac{dA_x}{dt} = \\ &= -q \left(\frac{\partial A_x}{\partial t} + \dot{x} \frac{\partial A_x}{\partial x} + \dot{y} \frac{\partial A_x}{\partial y} + \dot{z} \frac{\partial A_x}{\partial z} \right) \end{aligned}$$

- + Meanwhile,

$$\frac{\partial V}{\partial x} = q \frac{\partial \Phi}{\partial x} - q \left(\dot{x} \frac{\partial A_x}{\partial x} + \dot{y} \frac{\partial A_y}{\partial x} + \dot{z} \frac{\partial A_z}{\partial x} \right)$$

- + So

$$\begin{aligned} -\frac{\partial V}{\partial x} + \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}} \right) &= q \left(\frac{\partial \Phi}{\partial x} + \frac{\partial A_x}{\partial t} \right) \\ &\quad + q \left[\dot{y} \left(\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y} \right) + \dot{z} \left(\frac{\partial A_z}{\partial x} - \frac{\partial A_x}{\partial z} \right) \right] \end{aligned}$$

$$= +q E_x + q \dot{y} B_z - q \dot{z} B_y$$

+ This is indeed the right component of the force we want.

- Therefore, in Cartesian coords, $\frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}_i} \right) = -\frac{\partial V}{\partial x_i} + \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}_i} \right)$
 $\Rightarrow \frac{d}{dt} \left(\frac{\partial V}{\partial \dot{x}_i} \right) - \frac{\partial V}{\partial x_i} = 0$

The proof readily extends to generalized coordinates as above
