

# Weak Interactions

## ⊙ $W^\pm$ boson interactions ("Charged Weak")

- One of the force carriers is the  $W^\pm$  boson
  - It is charged and not its own antiparticle (ie,  $W^+$  and  $W^-$  are each other's antiparticle)
  - It is massive (mass =  $M_W$ )

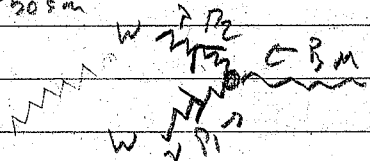

## - Feynman Rules for a massive, charged $W^\pm$

- An external line comes with polarizations
  - + Must have 4 rules
  - $\vec{p} \rightarrow \text{incoming}$  =  $W^+$  incoming,  $\vec{p} \rightarrow \text{outgoing}$  =  $W^+$  outgoing
  - $\vec{p} \rightarrow \text{incoming}$  =  $W^-$  incoming,  $\vec{p} \rightarrow \text{outgoing}$  =  $W^-$  outgoing
  - + Completeness relation is modified b/c there are 3 polarizations

$$\sum_{\lambda=1}^3 \epsilon_\mu \epsilon_\nu^* = -g_{\mu\nu} + p_\mu p_\nu / M_W^2$$

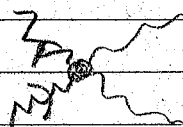

- Propagator is  $\frac{\vec{p} \rightarrow}{\circlearrowleft} = \frac{-i(g_{\mu\nu} - p_\mu p_\nu / M_W^2)}{p^2 - M_W^2}$

- Vertices with photons (that is what charge means!)
  - + 3-boson

$$= ie [g_{\mu\nu} (p_1 - p_2)_\mu + g_{\mu\nu} (p_2 - p_3)_\nu + g_{\mu\nu} (p_3 - p_1)_\mu]$$

+ 4-boson

$$= -i\lambda$$

## - Vertices with Fermions

- Due to charge, the  $W^\pm$  interactions change the particle type, ie charged lepton to neutrino

- The vertex is "vector minus axial" or "left-handed"

- The vertices for leptons are

$$\begin{array}{c}
 l^- \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 \bar{\nu}_l
 \end{array}
 \quad \text{or} \quad
 \begin{array}{c}
 \nu_l \\
 \swarrow \\
 \text{---} w^+ \\
 \searrow \\
 l^-
 \end{array}
 = \frac{-ig_w}{2\sqrt{2}} \gamma^\mu (1-\gamma^5)$$

- For quarks, they are almost within generations

$$\begin{array}{c}
 d' \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 u
 \end{array}
 \quad
 \begin{array}{c}
 s' \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 c
 \end{array}
 \quad \text{etc}$$

- + But that's not quite right! The weak force sees "primed" negatively charged quarks. We get all 9 possible interactions

$$\begin{array}{c}
 d \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 u
 \end{array}
 = \frac{-ig_w}{2\sqrt{2}} V_{ud} \gamma^\mu (1-\gamma^5)$$

$$\begin{array}{c}
 s \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 u
 \end{array}
 = \frac{-ig_w}{2\sqrt{2}} V_{us} \gamma^\mu (1-\gamma^5), \quad \text{etc}$$

- +  $V_{ij}$  = Cabibbo-Kobayashi-Maskawa (CKM) matrix

- + This allows many weak decays, etc.

- + Means that the "true" quark flavors seen as mass eigenstates, etc, are not the weak states

- Neutrino oscillations

- + The vertices above are not the whole story

- + In reality, the "true" neutrino mass eigenstates are  $\nu_1, \nu_2, \nu_3$ . The "flavor" states  $\nu_e, \nu_\mu, \nu_\tau$  are superpositions

- + Vertices are

$$\begin{array}{c}
 e^- \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 \nu_1
 \end{array}
 \quad
 \begin{array}{c}
 e^- \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 \nu_2
 \end{array}
 \quad
 \begin{array}{c}
 e^- \\
 \swarrow \\
 \text{---} w^- \\
 \searrow \\
 \nu_3
 \end{array}$$

- Processes

o Muon decay

o Neutron decay

o Neutral Weak Interactions (Z interactions)

- The lines look like those for  $W^\pm$ , except the Z is its own antiparticle

- There are lots of Z + W interactions

- The Z interaction does not change fermion type

$$f \begin{array}{c} \nearrow \\ \searrow \end{array} \gamma_\mu Z = \frac{-ig_Z}{2} \gamma_\mu (C_V^f - C_A^f \gamma^5)$$

where  $C_V^f, C_A^f$  are coefficients depending on fermion type. See table 9.1
