Numeration systems

- ▶ A **numeration system** is an increasing sequence of integers $U = (U_n)_{n \geq 0}$ such that
 - ▶ $U_0 = 1$ and
 - ▶ $C_U := \sup_{n \geq 0} [U_{n+1}/U_n] < \infty$.
- ▶ U is **linear** if it satisfies a linear recurrence relation over \mathbb{Z} .

Greedy representations

- ▶ A **greedy representation** of a non-negative integer n is a word $w = w_{\ell-1} \cdots w_0$ over $\{0, 1, \dots, C_U - 1\}$ such that

$$\sum_{i=0}^{\ell-1} w_i U_i = n,$$

and for all j

$$\sum_{i=0}^{j-1} w_i U_i < U_j.$$

- ▶ $\text{rep}_U(n)$ is the greedy representation of n with $w_{\ell-1} \neq 0$.

Recognizable sets

- ▶ A set X of integers is **U -recognizable** if $\text{rep}_U(X)$ is accepted by a finite automaton.
- ▶ If X is U -recognizable, then U is linear.
- ▶ The converse is not true in general.
- ▶ If $\text{rep}_U(\mathbb{N})$ is regular then let \mathcal{A}_U be the minimal automaton accepting $0^* \text{rep}_U(\mathbb{N})$.
- ▶ $\mathcal{A}_U = (Q_U, \{0, \dots, C_U - 1\}, \delta_U, q_{U,0}, F_U)$

The Fibonacci numeration system

- ▶ $U_{n+2} = U_{n+1} + U_n$ ($U_0 = 1, U_1 = 2$)
- ▶ \mathcal{A}_U accepts all words that do not contain 11.

The ℓ -bonacci numeration system

- ▶ $U_{n+l} = U_{n+l-1} + U_{n+l-2} + \cdots + U_n$
- ▶ $U_i = 2^i, i \in \{0, \dots, \ell - 1\}$
- ▶ \mathcal{A}_U accepts all words that do not contain 1^ℓ .

Bertrand numeration systems

- ▶ **Bertrand numeration system:** w is in $\text{rep}_U(\mathbb{N})$ if and only if $w0$ is in $\text{rep}_U(\mathbb{N})$.
- ▶ E.g., the ℓ -bonacci system is Bertrand.

A non-Bertrand system

- ▶ $U_{n+2} = U_{n+1} + U_n, (U_0 = 1, U_1 = 3)$
- ▶ $(U_n)_{n \geq 0} = 1, 3, 4, 7, 11, 18, 29, 47, \dots$
- ▶ 2 is a greedy representation but 20 is not.

β -expansions

- ▶ Bertrand systems are associated with β -expansions.
- ▶ Let $\beta > 1$ be a real number.
- ▶ The β -expansion of a real number $x \in [0, 1]$ is the lexicographically greatest sequence $d_\beta(x) := (t_i)_{i \geq 1}$ over $\{0, \dots, \lceil \beta \rceil - 1\}$ satisfying

$$x = \sum_{i=1}^{\infty} t_i \beta^{-i}.$$

Parry numbers

- ▶ If $d_\beta(1) = t_1 \cdots t_m 0^\omega$, with $t_m \neq 0$, then $d_\beta(1)$ is **finite**.
- ▶ In this case $d_\beta^*(1) := (t_1 \cdots t_{m-1}(t_m - 1))^\omega$.
- ▶ Otherwise $d_\beta^*(1) := d_\beta(1)$.
- ▶ If $d_\beta^*(1)$ is ultimately periodic, then β is a **Parry number**.

The Parry automaton

- ▶ Let $\text{Fact}(D_\beta)$ be the set of all words w lexicographically less than or equal to the prefix of $d_\beta^*(1)$ of length $|w|$.
- ▶ For β Parry, let \mathcal{A}_β be the minimal finite automaton accepting $\text{Fact}(D_\beta)$.

An example of the automaton \mathcal{A}_β

- ▶ Let β be the largest root of $X^3 - 2X^2 - 1$.
- ▶ $d_\beta(1) = 2010^\omega$ and $d_\beta^*(1) = (200)^\omega$.
- ▶ This automaton also accepts $\text{rep}_U(\mathbb{N})$ for U defined by $U_{n+3} = 2U_{n+2} + U_n$, $(U_0, U_1, U_2) = (1, 3, 7)$.

Characterization of Bertrand systems

Theorem (Bertrand)

A system U is Bertrand if and only if there is a $\beta > 1$ such that $0^* \text{rep}_U(\mathbb{N}) = \text{Fact}(D_\beta)$ (that is, $A_U = A_\beta$).

The dominant root condition

- ▶ U satisfies the **dominant root condition** if

$$\lim_{n \rightarrow \infty} U_{n+1}/U_n = \beta \text{ for some real } \beta > 1.$$

- ▶ β is the **dominant root** of the recurrence.
- ▶ E.g., Fibonacci: dominant root $\beta = (1 + \sqrt{5})/2$

A system with an integral dominant root

- ▶ $U_{n+1} = 3U_n + 2, (U_0 = 1)$
- ▶ dominant root $\beta = 3$

Observations and questions

- ▶ Previous example: two strongly connected components.
- ▶ One component is a loop labeled by 0.
- ▶ In general, when are there more than one strongly connected component?
- ▶ What do these components look like?

The main strongly connected component

Theorem

Let U be a linear numeration system such that $\text{rep}_U(\mathbb{N})$ is regular.

- (i) The automaton \mathcal{A}_U has a non-trivial strongly connected component \mathcal{C}_U containing the initial state.
- (ii) If p is a state in \mathcal{C}_U , then there exists $N \in \mathbb{N}$ such that $\delta_U(p, 0^n) = q_{U,0}$ for all $n \geq N$. In particular, one cannot leave \mathcal{C}_U by reading a 0.

The main strongly connected component

Theorem (cont'd.)

- (iii) If \mathcal{C}_U is the only non-trivial strongly connected component of \mathcal{A}_U , then $\lim_{n \rightarrow \infty} U_{n+1} - U_n = \infty$.
- (iv) If $\lim_{n \rightarrow \infty} U_{n+1} - U_n = \infty$, then $\delta_U(q_{U,0}, 1)$ is in \mathcal{C}_U .

Other strongly connected components

Theorem (cont'd.)

Suppose U has a dominant root $\beta > 1$. If \mathcal{A}_U has more than one non-trivial strongly connected component, then any such component other than \mathcal{C}_U is a cycle all of whose edges are labelled 0.

An example with two components

- ▶ Let $t \geq 1$.
- ▶ Let $U_0 = 1$, $U_{tn+1} = 2U_{tn} + 1$, and
- ▶ $U_{tn+r} = 2U_{tn+r-1}$, for $1 < r \leq t$.
- ▶ E.g., for $t = 2$ we have $U = (1, 3, 6, 13, 26, 53, \dots)$.
- ▶ Then $0^* \text{rep}_U(\mathbb{N}) = \{0, 1\}^* \cup \{0, 1\}^* 2(0^t)^*$.
- ▶ The second component is a cycle of t 0's.

Relationship with \mathcal{A}_β

Theorem (cont'd.)

Suppose U has a dominant root $\beta > 1$. There is a **morphism of automata** Φ from \mathcal{C}_U to \mathcal{A}_β .

Φ maps the states of \mathcal{C}_U onto the states of \mathcal{A}_β so that

- ▶ $\Phi(q_{U,0}) = q_{\beta,0}$,
- ▶ for all states q and all letters σ such that q and $\delta_U(q, \sigma)$ are in \mathcal{C}_U , we have $\Phi(\delta_U(q, \sigma)) = \delta_\beta(\Phi(q), \sigma)$.

An example

- ▶ Recall the Bertrand system defined by $U_{n+3} = 2U_{n+2} + U_n$, $(U_0, U_1, U_2) = (1, 3, 7)$.
- ▶ $d_\beta(1) = 2010^\omega$ and $d_\beta^*(1) = (200)^\omega$.
- ▶ $\mathcal{A}_U = \mathcal{A}_\beta$.

Changing the initial conditions

We change the initial values to $(U_0, U_1, U_2) = (1, 5, 6)$.

The morphism Φ

Φ maps $\{a, b, c\} \rightarrow \{1\}$; $\{d, e\} \rightarrow \{2\}$; and $\{f\} \rightarrow \{3\}$.

Other results

- ▶ When U has a dominant root $\beta > 1$, we can say more.
- ▶ E.g., if \mathcal{A}_U has more than one strongly connected component, then $d_\beta(1)$ is finite.
- ▶ We can also give sufficient conditions for \mathcal{A}_U to have only one strongly connected component and sufficient conditions for \mathcal{A}_U to have more than one strongly connected component.
- ▶ When U has no dominant root, the situation is more complicated.

A system with no dominant root

- ▶ $U_{n+3} = 24U_n, (U_0, U_1, U_2) = (1, 2, 6)$
- ▶ 3 strongly connected components

A system with no dominant root

- ▶ $U_{n+4} = 3U_{n+2} + U_n$, $(U_0, U_1, U_2, U_3) = (1, 2, 3, 7)$
- ▶ U_{n+1}/U_n does not converge, but
- ▶ $\lim_{n \rightarrow \infty} U_{2n+2}/U_{2n} = \lim_{n \rightarrow \infty} U_{2n+3}/U_{2n+1} = (3 + \sqrt{13})/2$

Application to state complexity

- ▶ If \mathbb{N} is U -recognizable then so is $m\mathbb{N}$.
- ▶ Alexeev (2004) gave an exact formula for the number of states of the minimal automaton accepting the b -ary representations of the multiples of m .
- ▶ We consider the same problem for other numeration systems.

The integer bases

Theorem (Alexeev 2004)

Let $\lambda(x, y) = \frac{x}{\gcd(x, y)}$. The number of states of the minimal automaton accepting the base b representations of the multiples of m is

$$\lambda(m, b^A) + \sum_{i=0}^{A-1} \lambda(b^i, m),$$

where A is the least non-negative integer i for which $\lambda(m, b^i) - \lambda(m, b^{i+1}) < \lambda(b^i, m)$.

The Hankel matrix

- ▶ Let $U = (U_n)_{n \geq 0}$ be a numeration system.
- ▶ For $t \geq 1$ define

$$H_t := \begin{pmatrix} U_0 & U_1 & \cdots & U_{t-1} \\ U_1 & U_2 & \cdots & U_t \\ \vdots & \vdots & \ddots & \vdots \\ U_{t-1} & U_t & \cdots & U_{2t-2} \end{pmatrix}.$$

- ▶ For $m \geq 2$, define $k_{U,m}$ to be the largest t such that $\det H_t \not\equiv 0 \pmod{m}$.

Calculating $k_{U,m}$

- ▶ $U_{n+2} = 2U_{n+1} + U_n$, $(U_0, U_1) = (1, 3)$
- ▶ $(U_n)_{n \geq 0} = 1, 3, 7, 17, 41, 99, 239, \dots$
- ▶ $(U_n \bmod 2)_{n \geq 0}$ is constant and trivially satisfies the recurrence relation $U_{n+1} = U_n$ with $U_0 = 1$.
- ▶ Hence $k_{U,2} = 1$.
- ▶ Mod 4 we find $k_{U,4} = 2$.

A system of linear congruences

- ▶ Let $k = k_{U,m}$.
- ▶ Let $\mathbf{x} = (x_1, \dots, x_k)$.
- ▶ Let $S_{U,m}$ denote the number of k -tuples \mathbf{b} in $\{0, \dots, m-1\}^k$ such that the system

$$H_k \mathbf{x} \equiv \mathbf{b} \pmod{m}$$

has at least one solution.

Calculating $S_{U,m}$

- ▶ $U_{n+2} = 2U_{n+1} + U_n$, $(U_0, U_1) = (1, 3)$
- ▶ Consider the system

$$\begin{cases} 1x_1 + 3x_2 \equiv b_1 \pmod{4} \\ 3x_1 + 7x_2 \equiv b_2 \pmod{4} \end{cases}$$

- ▶ $2x_1 \equiv b_2 - b_1 \pmod{4}$
- ▶ For each value of b_1 there are at most 2 values for b_2 .
- ▶ Hence $S_{U,4} = 8$.

Properties of the automata we consider

- (H.1) \mathcal{A}_U has a single strongly connected component \mathcal{C}_U .
- (H.2) For all states p, q in \mathcal{C}_U with $p \neq q$, there exists a word x_{pq} such that $\delta_U(p, x_{pq}) \in \mathcal{C}_U$ and $\delta_U(q, x_{pq}) \notin \mathcal{C}_U$, or vice-versa.

General state complexity result

Theorem

Let $m \geq 2$ be an integer. Let $U = (U_n)_{n \geq 0}$ be a linear numeration system such that

- (a) \mathbb{N} is U -recognizable and \mathcal{A}_U satisfies (H.1) and (H.2),
- (b) $(U_n \bmod m)_{n \geq 0}$ is purely periodic.

The number of states of the trim minimal automaton accepting $0^* \text{rep}_U(m\mathbb{N})$ from which infinitely many words are accepted is $|\mathcal{C}_U| S_{U,m}$.

Result for strongly connected automata

Corollary

If U satisfies the conditions of the previous theorem and \mathcal{A}_U is strongly connected, then the number of states of the trim minimal automaton accepting $0^* \text{rep}_U(m\mathbb{N})$ is $|\mathcal{C}_U|S_{U,m}$.

Result for the ℓ -bonacci system

Corollary

For U the ℓ -bonacci numeration system, the number of states of the trim minimal automaton accepting $0^* \text{rep}_U(m\mathbb{N})$ is ℓm^ℓ .

Further work

- ▶ Analyze the structure of \mathcal{A}_U for systems with no dominant root.
- ▶ Remove the assumption that U is purely periodic in the state complexity result.
- ▶ Big open problem: Given an automaton accepting $\text{rep}_U(X)$, is it decidable whether X is an ultimately periodic set?

The End
